1). Remove Button (Favourites Page)

The favourites page which lists each movie favoured by the user features a button on each movie card which allows for the user to remove a movie directly from the list itself. This was achieved by simply reusing the `removeFavourites` method and applying it to a button on the card.

2). Dark Theme

The application features an app-wide dark theme which was chosen to give the app a more professional finish. Implementation was achieved by minor alterations to `global.scss`, as the colour palette was pre-made by Ionic, thus uncommenting `dark.always.css` achieved the desired change.

3). Grid Layout

All of the cards containing the movie, cast, and crew images and names were changed from a list into a grid layout, allowing for more cards to be displayed on larger screens, making better use of the page layout, and making the application neater in general. This was achieved by creating a `.card-grid` class in `global.scss` and then wrapping it around the various card lists on each page, allowing the grid to be defined once then applied uniformly across each page.

4). Reusable Navbar Component

The application features a single, reusable navbar component. Before it was implemented, the navbar was hardcoded into each page individually, which led to inconsistencies with how the navigation buttons rendered. To rectify this, and to clean up the code, the navbar code was extracted into its own dedicated component and stored in the `NavbarComponent` class, which is then included in every page via its `<app-navbar>` tag. @Input technique sourced from Angular.dev (Angular.dev, 2026).

5). Combined API Requests

As many of the pages on the application required two separate pieces of data, notably the Movie Details page which features the movie data, as well as the cast/crew data, a combined API request allows for all of the details to be fetched on a single request, reducing the load time and guaranteeing that all data arrives at the same time. This feature was implemented by

adding the `append_to_response` parameters to the API requests, which was sourced directly from TMDB (TMDB, 2026).
